**Abstract.** Designing reliable and highly available distributed applications typically requires data to be replicated over geo-distributed stores. But, such architectures force application developers to make an undesirable tradeoff between ease of reasoning, possible when replicated data is required to be strongly consistent, and performance, possible only when such guarantees are weakened. Unfortunately, undesirable behaviors may arise under weak consistency that can violate application correctness, forcing designers to either implement ad-hoc mechanisms to avoid these anomalies, or choose to run applications using stronger levels of consistency than necessary. The former approach introduces unwanted complexity, while the latter sacrifices performance.

In this paper, we describe a lightweight runtime verification system that relieves developers from having to make such tradeoffs. Instead, our approach leverages declarative axiomatic specifications that reflect the necessary constraints any correct implementation must satisfy to guide a runtime consistency enforcement mechanism. This mechanism guarantees a *provably optimal* strategy that imposes no additional communication or blocking overhead beyond what is required to satisfy the specification, allowing distributed operations to run in a *provably safe* environment. Experimental results show that the performance of our automatically derived mechanisms is better than both specialized hand-written protocols and common store-offered consistency guarantees, providing strong evidence of its practical utility.

**Keywords:** runtime safety enforcement, weak consistency, distributed systems, Haskell

## 1 Introduction

Historically, the *de facto* system abstraction for developing distributed programs has always included the ACID<sup>1</sup> properties. These properties, guarantee replication transparency (i.e. requiring distributed systems to *appear* as a single compute and storage server to users), and have resulted in development of standardized implementation and reasoning techniques around *strongly consistent* (SC) distributed stores. Although strong notions of consistency, are ideal for development and reasoning about distributed applications, they require extensive

---

<sup>1</sup> Atomicity, Consistency, Isolation and Durability

synchronization overhead which is unacceptable for web-scale applications that wish to be “always-on” despite network partitioning. Applications are therefore usually designed to tolerate certain *inconsistencies*, in exchange for availability and low-latency. An extreme example is *eventual consistency* (EC), where the local state of each node at all time, only represents an *unspecified order* of an *unspecified subset* of the set of all updates submitted to the system globally. Applications that cannot tolerate the anomalous behaviors allowed under EC, may choose to use various stronger instantiations, that are collectively referred to as *weak consistency* guarantees. Unfortunately, weak notions of consistency, are closely tied to the specific data-store implementations, and in very few cases, such as *causal consistency* (CC), for which there exists relatively standard definitions and known implementation techniques, users are usually offered with unnecessary levels of consistency and potential performance loss<sup>2</sup>. In order to face this problem, developers are forced to inject their code with *ad-hoc* anomaly tolerance mechanisms that are closely tied to the application logic and conflates it with concerns orthogonal to its semantics. To illustrate this problem, we will present an example in section 3, where we introduce a simple distributed application developed on top of an off-the-shelf eventually consistent data-store (ECDS), and explain how it must be re-engineered from the scratch in order to preempt certain undesired behaviors (i.e. enforce fine-grained weak consistency requirements). As we will see, the ad-hoc nature of such mechanisms confounds standardization, and complicates reasoning, maintainability and reusability of the applications.

In this paper, we propose an alternative to the aforementioned approaches that overcomes their weaknesses. SYNCOPE is a lightweight runtime system for Haskell that allows application developers to take advantage of weak consistency without having to re-engineer their code to accommodate anomaly preemption mechanisms. The key insight that drives SYNCOPE’s design is that the hardness of reasoning about the integrity of a distributed application stems from conflating application logic with the consistency enforcement logic, and reasoning about both *operationally*. By separating application semantics from consistency enforcement semantics, admitting operational reasoning for the former, and declarative reasoning for the latter programmers are liberated from having to worry about implementation details of preemption mechanisms, and instead focus on reasoning about application semantics, under the assumption that specified consistency requirements are automatically enforced by the data store at runtime. Our approach admits declarative reasoning for consistency enforcement via a specification language that allows programmers formally specify the consistency requirements of their application. The design of our specification language is based on the observation that all anomalous behaviors allowed under EC, occur as the result of nodes executing operations, before a certain set of *dependencies* arrive at that node. Users in SYNCOPE, can specify arbitrary dependency relations between updates, and the runtime monitoring system working on top

---

<sup>2</sup> In fact, CC is the strongest consistency guarantee that remains available under network partitioning

of each ECDS replica, guarantees that an operation will only proceed if it can witness all of its dependencies. For example, *lost-updates*, which is a very well known anomaly under EC, occurs when an operation from a session is routed to a replica different than the replica that served the earlier operations of the same session (because of transient system properties, such as load balancing or network partitions) and is successfully executed, without witnessing the update from those earlier operations. In this case, the dependency of the operations can be defined as the updates from *all previous operations from the same sessions*, and SYNCOPE is guaranteed to temporarily block operations until all such dependencies become available at a replica.

To summarize the contributions of this paper: (i) We propose a specification language to express the fine-grained consistency requirements of applications in terms of the dependencies between operations. (ii) We describe a generic consistency enforcement runtime that analyzes each operation’s consistency specification, and ensures that its dependencies are satisfied before it is executed. We formalize the operational semantics of the runtime, and prove its correctness and optimality (including *minimum blocking* and *minimum staleness*) guarantees. (iii) We describe an implementation of our specification language and consistency enforcement runtime in a tool called SYNCOPE, which works on top of an off-the-shelf EC data store. We evaluate SYNCOPE over realistic applications and microbenchmarks, and present results demonstrating the performance benefits of making fine-grained distinctions between consistency guarantees, and the ease of doing so via our specification language.

The remainder of the paper is organized as follows. A system model that describes the key notions of consistency and replication is presented in Sec. 2. In Sec. 3 we provide a detailed example to further motivate the problem. In Sec. 4 and Sec. 5, we formally present our specification language and the high level operational semantics of the runtime system, with correctness and optimality theorems. Sec. 6 elaborates on the algorithmic aspects of our runtime that is key to its efficient realization. Sec. 7 describes implementation of SYNCOPE, and evaluates its applicability and practical utility. Related works and conclusion are presented in Sec. 8 and Sec. 9

## 2 System Model

A data store in our system model is a collection of *replicas* ( $\#1, \#2, \dots$ ), each of which maintains a copy of a set of replicated *data object* ( $\mathbf{x}, \mathbf{y}, \dots$ ). Each data object includes maintains a *state value* ( $\mathbf{v}, \mathbf{v}', \dots$ ) and is equipped with a set of *operations* ( $\mathbf{op}, \mathbf{op}', \dots$ ). Operations may read the state of an object residing in a replica, and modify it by generating *update effects* ( $\eta, \eta', \dots$ ). Update effects or simply effects are asynchronously sent to all other replicas, where, by using a user-defined function, are *applied* to the state of the object instance in the recipient replica. Fig. 1a and 1b illustrate this process, where the example shows how effects are locally created and remotely applied.

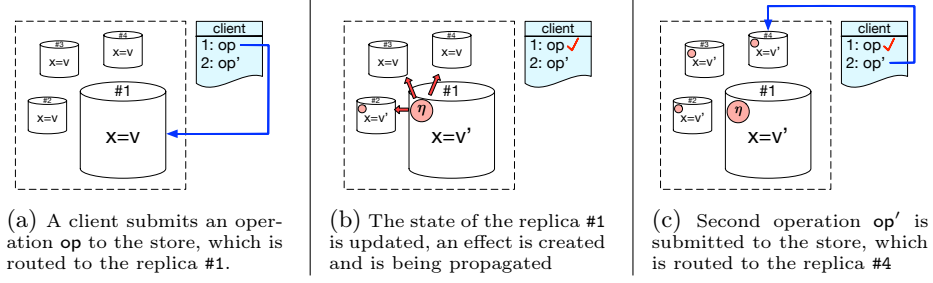

Fig. 1: system model of SYNCOPE

Observe that in our system model, there is no direct synchronization between replicas when an operation is executed, which means concurrent and possibly conflicting updates can be generated at different replicas. We require the user-defined *apply* function to implement a conflict resolution strategy for replicas to eventually converge. This model admits all inconsistencies and anomalies associated with eventual consistency [1, 2], and our goal is equip applications and implementations with mechanisms to specify and prevent such inconsistencies.

Clients in our model, interact with the store by invoking operations on objects. A *session* is a sequence of operations invoked by a particular client. Consequently, operations (and effects) can be uniquely identified by the *session id* that invoked them, and their *sequence number* in that particular session, which is used by replicas, to record the set of all updates locally applied. Since, the data store is concurrently accessed by a typically large number of clients, and as a result of the load balancing regulations, operations (even from the same session) might be routed to different replicas (Fig. 1a and 1c).

Lastly, we define two relations over effects created in the store. *Session order* (*so*) is an irreflexive, transitive relation that relates an effect to all subsequent effects from the same session. Moreover, we define *visibility* (*vis*) as an irreflexive and assymmetric relation that relates an effects to all others that are influenced by it (witnessed its update) at the time of their generation. For example, in Fig. 1c  $\text{vis}(\eta, \eta')$  holds, since  $\eta$  (the effect of  $op$ ) has already been delivered and applied to the replica #4, when  $op$  is executed and thus has influenced generation of  $\eta'$ .

### 3 Motivation

#### 3.1 Replicated Data Types in ECDS

To provide further motivation, consider a highly available (low latency) application for managing comments on posts in a photo sharing web site. Fig. 2a presents a simple Haskell implementation of such an application cognizant of our system model.

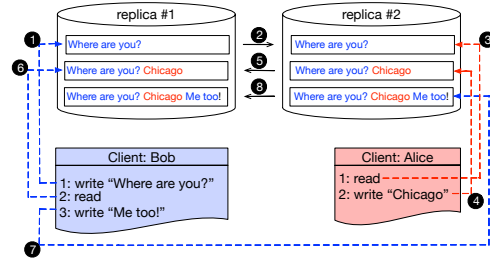

In the implementation, **Effect** and **State** strings are respectively defined as the text of a single comment, and the concatenation of all visible comments associated with a post. A new **Effect** is generated every time a user wants to

```

1 type Effect = String
2 type State = String
3
4 read :: State -> (String, Maybe Effect)
5 read s = (s, Nothing)
6
7 write :: String -> ((), Maybe Effect)
8 write comment = ((), Just comment)
9
10 apply :: State -> Effect -> State
11 apply s comment = s ++ comment

```

(a) A simple implementation

(b) Example execution

Fig. 2: A distributed application for comment section management

comment on a post by calling the `write` function, and a `read` call simply returns the `State` of the object at the serving replica. The `apply` function, simply returns the updated state of the replica, which is a concatenation of the old state and a given effect. For perspicuity, we omit any conflict resolution strategy in the code; however, developers (using roll-backs, etc) can design the `apply` function to resolve conflicting concurrent updates as they desire.

An example of how users interact with this application is presented in Fig. 2b, where Alice and Bob are invoking operations on an object (here, a photo of Alice in Chicago), and the chronological order of events is given in black circles. At time ❶, Bob writes a comment, which is routed to replica #1, whose effect is then propagated and delivered to replica #2 at ❷; where Alice's first read operation is routed to at ❸. Alice and Bob then keep talking through more read and write events, while updates are propagated between the two replica.

As mentioned before, lost-updates, is a well known undesirable behavior admitted by ECDS. An example of such anomaly can occur here if at time ❹, Bob is temporarily disconnected from both replicas in the figure, and his read operation is routed to another replica that has not yet received any updates from #1 or #2. Consequently, Bob cannot see his first comment and would retry submitting it, assuming the first time it was failed.

### 3.2 Ad-hoc Anomaly Prevention

A known technique to prevent the above anomaly, is to tag each effect using a unique identifier as mentioned in Sec. 2. Using these tags, replicas will be able to track all locally available effects, and temporarily *block* operations, until all the preceding effects from the same session arrive at the replica. For example, the replica #3 that receives Bob's read in the example scenario, can simply postpone its execution until all dependencies arrive.

In order to reduce the overhead of tracking dependencies per operation, the above idea is further realized using another technique called *filtration*, which is based on separating the locally available effects at each replica that have not been applied to the state yet and those who have. By this separation, in the

above example each replica can maintain a *safe environment* for operations (e.g. using a soft-state cache), that contains an effect only if it also contains all the previous effects from the same session. This way, an operation can proceed, when the effect of the very exact previous operation from the same session is already applied to the state (which transitively yields the presence of all dependencies).

We present a new version of our running example in appendix A, which is modified to tolerate the lost-update anomaly by implementing the blocking mechanism in the `read` function and the filtration in the `apply` function as explained above. Unfortunately, these modifications require fundamental and pervasive changes to the original code including almost all type and function definitions. Additionally, the changes are heavily tangled with application logic, complicating reasoning and hampering correctness arguments.

A major drawback of this approach in stores that do not admit metadata queries (e.g. Cassandra), is the *lost histories*[3] problem. To face this problem, for each new session joining, the replicas must perform a table alteration at the data store level, to accommodate the data on the newly joined session. This requires strong synchronization of replicas, degrading application performance and availability. Moreover, to make the matter worse, new anomalies are constantly found in the systems after the design phase, which require non-trivial, further polluting, ad-hoc solutions that leave the old implementation obsolete.

### 3.3 An Alternative

We now present our generic consistency management tool. SYNCOPE allows developers to define a consistency level for each operation *a priori*, and rely on the runtime system for its satisfaction. Our approach is consisted of generalized blocking and filtration mechanisms, which admits arbitrary user-defined dependence relations for each operation and maintains a multi-consistent *shim layer* on top of each ECDS replica.

The SYNCOPE shim layer maintains multiple safe environments ( $E_1, E_2, \dots$ ) by periodic (or on-demand) reads from the underlying ECDS database, and adding effects to each environment, only if its dependencies have already been added (Fig. 3). SYNCOPE realizes this idea efficiently, using a simple tagging mechanism that represents effects in an environment by giving them a tag associated with that environment. Each operation in SYNCOPE only witnesses its associated environment, and is blocked by the runtime system, if the necessary effects are not in there yet.

Users in our tool can specify arbitrary consistency guarantees in a language that is seeded with `so` and `vis` relations and allows them to define constraints on read operations, that can be used to synthesize appropriate filtration and blocking mechanisms. For example, the following *contract*, eliminates the possibility of lost-update anomaly, by establishing the appropriate condition under which an effect may become visible to the effect of the current operation,  $\hat{\eta}$ :

$$\psi_1 : \forall a. \xrightarrow{\text{so}} \hat{\eta} \Rightarrow a \xrightarrow{\text{vis}} \hat{\eta}$$

Fig. 3: SYNCOPE

$ \begin{aligned} r &\in \text{rel.seed} := \text{vis} \mid \text{so} \mid r \cup r \\ R &\in \text{relation} := r \mid R; r \mid \text{null} \\ \pi &\in \text{prop} := \forall a. a \xrightarrow{R} \hat{\eta} \Rightarrow a \xrightarrow{\text{vis}} \hat{\eta} \\ \psi &\in \text{spec} := \pi \mid \pi \wedge \pi \end{aligned} $	<table border="1"> <thead> <tr> <th>Guarantee</th><th>Contract</th></tr> </thead> <tbody> <tr> <td>RMW</td><td><math>\forall a. a \xrightarrow{\text{so}} \hat{\eta} \Rightarrow a \xrightarrow{\text{vis}} \hat{\eta}</math></td></tr> <tr> <td>MW</td><td><math>\forall a. a \xrightarrow{\text{so}; \text{vis}} \hat{\eta} \Rightarrow a \xrightarrow{\text{vis}} \hat{\eta}</math></td></tr> <tr> <td>MR</td><td><math>\forall a. a \xrightarrow{\text{vis}; \text{so}} \hat{\eta} \Rightarrow a \xrightarrow{\text{vis}} \hat{\eta}</math></td></tr> <tr> <td>2VIS</td><td><math>\forall a. a \xrightarrow{\text{vis}; \text{vis}} \hat{\eta} \Rightarrow a \xrightarrow{\text{vis}} \hat{\eta}</math></td></tr> </tbody> </table>	Guarantee	Contract	RMW	$\forall a. a \xrightarrow{\text{so}} \hat{\eta} \Rightarrow a \xrightarrow{\text{vis}} \hat{\eta}$	MW	$\forall a. a \xrightarrow{\text{so}; \text{vis}} \hat{\eta} \Rightarrow a \xrightarrow{\text{vis}} \hat{\eta}$	MR	$\forall a. a \xrightarrow{\text{vis}; \text{so}} \hat{\eta} \Rightarrow a \xrightarrow{\text{vis}} \hat{\eta}$	2VIS	$\forall a. a \xrightarrow{\text{vis}; \text{vis}} \hat{\eta} \Rightarrow a \xrightarrow{\text{vis}} \hat{\eta}$

Fig. 4: SYNCOPE Specification Language

## 4 Specification Language

The formal syntax of our specification language is presented in Fig. 4a, which allows definition of propositions (**prop**), FOL formulae that establish dependence relations between effects in order to determine the effects an operation should witness. The language is seeded with **so** and **vis**, respectively representing session order and visibility over effects, and defines a **relation** as a sequence<sup>3</sup> of relation seeds, representing dependencies between effects, which should be desugared as follows:

$$a \xrightarrow{r_1; \dots; r_k} b \iff \exists c. (a \xrightarrow{r_1; \dots; r_{k-1}} c \wedge c \xrightarrow{r_k} b) \quad (1)$$

Additionally, the language allows definition of **spec**, that is a conjunction of propositions, and is used to define safe environments that are free of *multiple* inconsistencies. Our language is crafted to capture fine-grained weak consistency requirements, including the famous session guarantees [2], presented in Fig 4b.

We finish this section by syntactically classifying contracts, and explaining how each of them requires different enforcement techniques.

**LB:** If the defined dependency relation for a contract ends with an **so**, i.e. is of the following form  $(\forall a. a \xrightarrow{r_1; r_2; \dots; \text{so}} \hat{\eta} \Rightarrow a \xrightarrow{\text{vis}} \hat{\eta})$ , we call it a *lower bound* (LB) contract, since it specifically defines the smallest set of effects that any operation should witness to maintain consistency, e.g. RMW and MR in Fig. 4b.

**UB:** Similarly, we define the *upper bound* (UB) contracts, as the ones with dependency relations ending with a **vis**. These contracts define constraints on the set of effects made visible to each operation, by enforcing that if an effect is being witnessed certain set of dependencies must also be witnessed.

Our consistency enforcement approach is based on blocking operations with LB contracts to make sure that they witness *all effects that they are supposed to*, and filtration for UB contracts to make sure that they would not witness *effects that they are not supposed to*. A combination of both approaches is also taken for contracts that are neither LB nor UB, i.e hybrid contracts.

## 5 Semantics

In this section, we present the consistency enforcement mechanism of SYNCOPE, abstracted as a formal operational semantics. Our approach is complete for the

<sup>3</sup> SYNCOPE also allows definition of the closure of relations, however we omitted them here for simplicity reasons

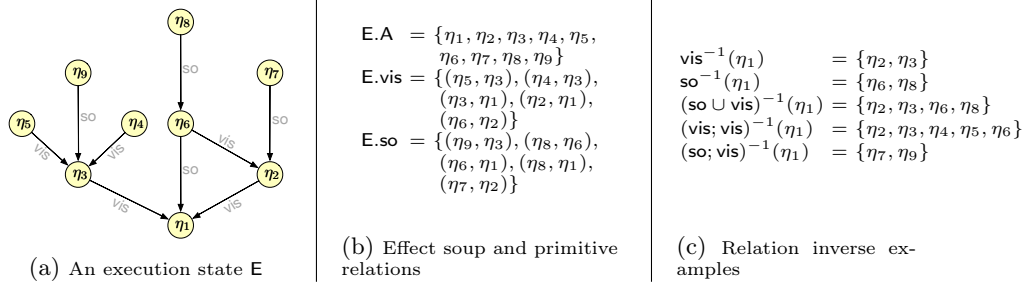

Fig. 5: A simple execution state

specification language defined in Sec. 4, however for better comprehensibility, here we present the semantics and the theorems parameterized over a non-hybrid contract consisting of one proposition. Therefore, in the rest of this section, we will assume a given contract  $\psi$  of the following form:

$$\psi = \forall a. a \xrightarrow{x_1; x_2; \dots; x_k} \hat{\eta} \Rightarrow a \xrightarrow{\text{vis}} \hat{\eta} \quad x_i \in \{\text{vis}; \text{so}\}$$

The operational semantics is defined via a small-step relation over *execution states*, which are tuples of the form  $E = (A, \text{vis}, \text{so})$ . The *effect soup*  $A$ , stands for the set of all effects produced in the system, and *primitive relations*  $\text{vis}, \text{so} \subseteq A \times A$ , respectively represent the visibility and session order among such effects. Figures 5a and 5b represent a simple execution state consisting of 9 effects with associated primitive relations<sup>4</sup>. We denote the subset of  $A$  consisting of effects that satisfy a certain condition as  $A_{(\text{condition})}$ .

Note that SYNCOPE's contracts are in fact constraints over execution states, where the domain of quantification is fixed to the effect soup  $A$ , and interpretation for  $\text{so}$  and  $\text{vis}$  relations (which occur free in the contract formulae) are also provided. Thus, execution states are potential models for any first-order formula expressible in the specification language. If an execution state  $E$  is in fact a valid model for a contract  $\psi$ , we say that  $E$  satisfies  $\psi$ , written as  $E \models \psi$ .

The reduction relation in the semantics is of the form  $(E, \text{op}_{<s, i>}) \xrightarrow{\mathbf{V}} (E', \eta)$ , which can be interpreted as the reduction of the initial execution state  $E$ , caused by a replica with a local set of effects  $\mathbf{V}$  when it executes  $\text{op}$ , which is the  $i^{\text{th}}$  operation from the session  $s$ . During this reduction step a new effect  $\eta$  is produced and added to the system, resulting in a new execution state  $E'$  consisting of a new effect soup and updated primitive relations.

## 5.1 Preliminaries

In this part, we will formally present the definitions and notations required to explain our operational semantics. We start by defining the interpretation of the *inverse* of a given  $R \in \text{relation}$ , under an execution state  $E$ , which represents the basis of our consistency enforcement mechanism. We previously mentioned

<sup>4</sup> we omit drawing transitive  $\text{so}$  edges (e.g. between  $\eta_8$  and  $\eta_1$ ) for better readability

our interpretation for seed relations between effects under  $E$ , which can now be trivially extended to their inverse as follows<sup>5</sup>:

$$\mathbf{r}^{-1}(S) = \bigcup_{b \in \mathbf{S}} \{a \mid (a, b) \in E.r\} \quad \mathbf{r} \in \{\mathbf{so}, \mathbf{vis}\} \quad (2)$$

Additionally, based on (1), we can extend the above definition to sequences of seed relations as well:

$$b \in (R'; \mathbf{r})^{-1}(a) \iff \exists c. c \in \mathbf{r}^{-1}(a) \wedge b \in (R')^{-1}(c) \quad (3)$$

Now, It might seem that the inverse of  $R$  is now ready to be defined using the two definitions above; however, definition (3) fails to capture the reality of our system model, where all computations are independently performed by replicas, which at any given moment, might have access to only a *subset of all produced effects* in the system. For example, consider  $(\mathbf{so}; \mathbf{vis})^{-1}(\eta_1)$  under the execution state presented in figure 5. In order to compute this set, based on (3) we have:

$$b \in (\mathbf{so}; \mathbf{vis})^{-1}(\eta_1) \iff \exists c. c \in \mathbf{vis}^{-1}(\eta_1) \wedge b \in (\mathbf{so})^{-1}(c)$$

Now, since there exist *mid-level* effects  $c = \eta_2$  and  $c = \eta_3$ , such that satisfy the above definition respectively for  $\eta_7$  and  $\eta_9$ , we can conclude:  $(\mathbf{so}; \mathbf{vis})^{-1}(\eta_1) = \{\eta_7, \eta_9\}$ . Now consider a replica that contains  $\{\eta_1, \eta_6, \eta_7, \eta_9\}$  at the moment, and wants to check if the dependencies of  $\eta_1$  are locally present or not. Even though based on the above definition, the answer is positive (since the replica does contain  $\{\eta_7, \eta_9\}$ ), but in reality the replica has no way of verifying it, since the mid-level effects  $\eta_2$  and  $\eta_3$  are not present at the replica yet.

To capture the above property, we now partially define the inverse of  $R$ , according to a set of available effects  $V$ , only if all the required mid-level effects are present in  $V$ . The following is our definition, based on (2) and a more strict version of (3):

$$b \in R_V^{-1}(a) \iff \begin{cases} \perp & \text{if } R = \text{null} \\ b \in \mathbf{r}^{-1}(a) & \text{if } R = \mathbf{r} \\ \exists c. c \in \mathbf{r}^{-1}(a) \wedge b \in (R')^{-1}(c) \wedge \mathbf{r}^{-1}(a) \subseteq V & \text{if } R = R'; \mathbf{r} \end{cases} \quad (4)$$

For example, in Fig. 5,  $(\eta_9 \in (\mathbf{so}; \mathbf{vis})_{\{\eta_1, \eta_3\}}^{-1}(\eta_1))$  holds, but  $(\eta_9 \notin (\mathbf{so}; \mathbf{vis})_{\{\eta_1\}}^{-1}(\eta_1))$ . As a result, we can now define a set  $V$  to be *self-contained* for a given effect  $\eta$ , written as  $\mathbb{SC}_\eta^R(V)$ , if  $V$  contains all the required mid-level effects to compute  $R$  inverse of  $\eta$  in totality. Formally:

$$\mathbb{SC}_\eta^R(V) \iff R_V^{-1}(\eta) = R_{E.A}^{-1}(\eta) \quad (5)$$

For example in Fig. 5,  $\mathbb{SC}_{\eta_1}^R(V)$  holds for an arbitrary  $R$  and for any  $V$  that is a superset of  $\{\eta_1, \eta_2, \eta_3, \eta_4, \eta_5\}$ .

Now, we define  $\text{trunc}()$  as a function that given  $R \in \text{relation}$ , removes the last element from the sequence (if there is any) in  $R$ , i.e.

$$\text{trunc}(R) = \begin{cases} \text{null} & \text{if } R = \mathbf{r} \quad \text{or} \quad R = \text{null} \\ R' & \text{if } R = R'; \mathbf{r} \end{cases} \quad (6)$$

<sup>5</sup> Note that when the input of an inversed relation is a singleton  $\{\eta\}$ , we drop the brackets and simply write it as  $\mathbf{r}^{-1}(\eta)$

### Auxiliary Definitions

$op \in \text{Oper. Name}$	$F_{op} \in \text{Op. Def.} := \mathcal{P}(\eta) \mapsto v$
$v \in \text{Ret. Val.}$	$A \in \text{Eff Soup} := \mathcal{P}(\eta)$
$s \in \text{Sess. ID}$	$\text{vis, so} \in \text{Relations} := \mathcal{P}((\eta, \eta))$
$\eta \in \text{Effect} := (s, op, v)$	$E \in \text{Exec State} := (A, \text{vis}, \text{so})$

### Auxiliary Reduction

$$S \vdash (E, op_{<s, i>}) \hookrightarrow (E', \eta)$$

[OPER]

$$\frac{S \subseteq A \quad F_{op}(S) = v \quad \eta \notin S \quad \eta = (s, op, v) \quad A' = A \cup \{\eta\} \quad \text{vis}' = \text{vis} \cup S \times \{\eta\} \quad \text{so}' = \text{so} \cup \{(\eta', \eta) \mid \eta' \in A_{(\text{SessID}=s)}\}}{S \vdash ((A, \text{vis}, \text{so}), op_{<s, i>}) \hookrightarrow ((A', \text{vis}', \text{so}'), \eta)}$$

### Operational Semantics

$$(E, op_{<s, i>}) \xrightarrow{V} (E', \eta)$$

[UB EXEC]

$$\frac{\mathbf{r}_k = \text{vis} \quad V \subseteq E.A \quad V' = [V]_{\max} \quad V' \vdash (E, op_{<s, i>}) \hookrightarrow (E', \eta)}{(E, op_{<s, i>}) \xrightarrow{V} (E', \eta)}$$

[LB EXEC]

$$\frac{\mathbf{r}_k = \text{so} \quad V \subseteq E.A \quad \mathbb{SC}_{\eta}^R(V) \quad R_V^{-1}(\eta) \subseteq V \quad V \vdash (E, op_{<s, i>}) \hookrightarrow (E', \eta)}{(E, op_{<s, i>}) \xrightarrow{V} (E', \eta)}$$

Fig. 6: Core Operational semantics of a replicated data store.

And finally, we define *closed subsets* of a given set  $V$ , as all subsets of  $V$  that are closed under  $(\text{trunc}(R)_V^{-1})$ , that also contain all the required mid-level effects to compute  $\text{trunc}(R)^{-1}$ . We also define the maxiamal element among such subsets next<sup>6</sup>:

$$\begin{aligned} \text{closed subsets} : V' \in [V] &\iff V' \subseteq V \wedge (\text{trunc}(R))_V^{-1}(V') \subseteq V' \wedge \mathbb{SC}_{\eta}^{\text{trunc}(R)}(V') \\ \text{maximally closed subset} : V' = [V]_{\max} &\iff V' \in [V] \wedge \nexists V'' \in [V]. |V''| > |V'| \end{aligned}$$

## 5.2 Core Operational Semantics

In this part we present our operational semantics, as a set of rules representing our consistency enforcement approach. Figure 6 presents the rules defining the auxiliary relation  $(\hookrightarrow)$  and then the small-step reduction relation  $(\xrightarrow{V})$  over execution states, where the latter is parametrized over a set  $V$ , which stands for the locally available set of effects at the replica taking the reduction step. Trivially,  $V$  is a subset of all effects in the system at the initial execution state, however, there is no other restrictions on  $V$ , since we only assume eventual consistency at the underlying store.

The rule [OPER] repestns the procedure of generating a new effect  $\eta$ , by witnessing a set of effects  $S$ , using a user-defined function  $F_{op}$ . We formally define an effect as a tuple  $\eta = (s, op, v)$ , representing the session and the operation

<sup>6</sup> We slightly abuse the previously defined notation in (4) and use a *set* of effects as the input to the inverse of  $R \in \text{relation}$ , which simply means the union of the results of apply the function for all the effects in the input set

name whose execution created  $\eta$ , and the value that the replica returns as the response to that operation. Moreover, the rule explains how the execution state changes after producing an effect at a replica. Specifically, in the new execution state, the effect soup  $A'$  contains the newly created effect  $\eta$ , the relation  $\text{vis}'$  captures the fact that all effects in the set  $S$  were made visible to  $\eta$ , and  $\text{so}'$  states that all effects from the same session as the current operation, that are already present in the system, should be in session order with  $\eta$  in the final execution state.

Now we explain the rules for reduction relation  $(\xrightarrow{V})$ , starting with  $[\text{UB EXEC}]$ , which represents the execution of an operation in a replica that updates the global state and produces a new effect under a UB contract. The rule requires operations to only witness  $V'$ , the maximally closed subset of  $V$ , or in other words, the rule governs replicas to create safe environments for operations, by filtering out effects that may cause anomalies.

The next rule,  $[\text{LB EXEC}]$ , represents the step taken when an operation is performed under an LB contract. The precondition  $R_V^{-1}(\eta) \subseteq V$  in the rule, ensures that the reduction happens only if the effects necessary to avoid the specified anomaly are present in  $V$ , assuming that  $V$  is a self contained set for the newly created effect,  $\eta$ . In other words, the rule requires replicas to block execution of an operation under an LB contract, if the replica is unable to verify the presence of all necessary dependent effects.

### 5.3 Soundness and Optimality

In this section we present our meta-theoretic results on the desired properties for our consistency enforcement mechanism. What follows is three theorems regarding the correctness of our approach, maximality of witnessed effects by each operation (i.e. minimum staleness) and the liveness guarantee of the system, given the eventual delivery of all effects to all replicas, which is guaranteed by the underlying ECDS. Detailed proofs of all theorems can be found in appendix B. Before presenting the theorems, we should define a  $\psi$ -consistent set of effects  $S$  under an execution state  $E$  as a set that is closed under  $R$ , i.e.

$$S \text{ is } \psi\text{-consistent} \iff \forall (\eta \in S). \forall (a \in E.A). R(a, \eta) \Rightarrow a \in S \quad (7)$$

**Theorem 1.** *For all reduction steps  $(E, op_{<s,i>}) \xrightarrow{V} (E', \eta)$ ,*

- (i) *If  $V$  is  $\psi$ -consistent under  $E$ , then  $V \cup \{\eta\}$  is  $\psi$ -consistent under  $E'$*
- (ii)  *$E' \models \psi[\eta/\hat{\eta}]$*

This theorem states the preservation of  $\psi$ -consistency at replicas under reduction steps and secondly, the correctness of the enforced consistency guarantee.

**Theorem 2.** *For all reduction steps  $(E, op_{<s,i>}) \xrightarrow{V} (E', \eta)$ , the set of effects made visible to  $\eta$  is maximal. i.e. for all  $a \in V$ , if  $\text{SC}_a^{\text{trunc}(R)}(V)$ , then*

$$(a, \eta) \notin E'.\text{vis} \Rightarrow (E'.A, E'.\text{vis} \cup \{a, \eta\}, E'.\text{so}) \not\models \psi[\eta/\hat{\eta}]$$

**Theorem 3.** *For all execution states  $E$ , if there exists a set of effects  $S \subseteq E.A$ , such that:*

$$S \vdash (E, op_{<s,i>}) \hookrightarrow (E', \eta) \quad \wedge \quad (S \cup \{\eta\} \text{ is } \psi\text{-consistent under } E')$$

*then there exist  $E''$ ,  $\eta'$  and  $V \subseteq E.A$  such that:  $((E, op_{<s,i>}) \xrightarrow{V} (E'', \eta'))$*

As a result of the above theorem the liveness of our operational semantics is guaranteed, since at least one set  $S$  with the desired properties, always exists<sup>7</sup> at any execution state.

## 6 Algorithm

In Sec. 5, we presented a high-level abstraction of our system behavior, where we explained *what* subset of effects at a replica, must be witnessed by every operations. In this section, we explain SYNCOPE's algorithm to efficiently maintain a *consistent cache*, in order to avoid redundancies in filtration mechanism.

SYNCOPE maintains a consistent cache on top of each replica, by periodic reads from the underlying ECDS, where an effect  $\eta$  is moved to the cache, only if the cache already includes  $\text{trunc}(R)_V^{-1}(\eta)$ . Consequently, all operations under UB contracts can be immediately executed by witnessing the cache, which is a closed subset (not necessarily maximal all the time) of effects present at the replica. Moreover, LB contracts can be satisfied, if operations are blocked until effects of all previous operations from the same session enter the cache, in which case current operation can proceed and witness *all* effects present at the replica.

Additionally, we implemented a simple memoization technique in SYNCOPE, that extends the binary notion of dependency presence to the *degree of dependency presence* (DDP), that represents the maximum *depth* of dependencies, whose presence have been verified so far. Consequently, when verifying the presence of dependencies for an effect fails, the runtime system can avoid redundant computations, next time it tries to verify the same property for the same effect. SYNCOPE's runtime, by performing periodic DDP refreshes, tries to assign larger numbers to each effect while more effects arrive at the replica. Specifically, at each refresh the *DDP* of an effect  $\eta$  is increased from  $i$  to  $i + 1$  if all effects in  $r_{i+1}^{-1}(\eta)$  already have *DDP* values at least equal to  $i$ .

For example, consider a contract with dependency relation  $R = \text{so}; \text{vis}; \text{so}$ , and a newly arrived effect  $\eta$  to the replica, whose DDP is initially set to 0. During the next refreshes,  $\eta$  is given the value 1, if all effects in  $\text{so}^{-1}(\eta)$  have DDP equal to 0 (i.e. are present at the replica). Similarly,  $\eta$  is given the value 2, if all effects in  $\text{vis}^{-1}(\eta)$  have DDP value of at least 1, which means that now  $(\text{so}; \text{vis})_V^{-1}(\eta)$  is now present at the replica and  $\eta$  can be safely added to the consistent cache (Fig. 7)

<sup>7</sup>  $S = E.A$ . This requires the preservation of  $\psi$ -consistency under the resuction step, that is already shown in theorem 1.

Fig. 7: Example of stepwise progress of effects before entering the cache

## 7 Evaluation

In this section we present an evaluation study of our implementation, including a report on benchmark applications that utilize fine-grained weak consistency requirements, expressible in our specification language. Fig. 8 presents seven of such programs, including individual data types as well as larger programs consisted of multiple data types.

Each program offers various operations, each of which is assigned a potentially different consistency requirement, representing the need for a multi-consistent environment for efficient execution of the programs. Surprisingly, we found no program requiring causal consistency; all known consistency anomalies that operations may be involved in, are expressible with simple contracts made of dependency relations of length 1 or 2, which differs from what was known in the context before, where all such operations were considered to require CC.

Additionally, in many cases we found operations that are involved in multiple anomalies, requiring simultaneous enforcement of different consistency guarantees, which shows the unfeasibility of hand-writing such guarantees, considering the vast set of known consistency anomalies. For example, consider the bank account application, which offers `deposit`, `withdraw` and `get_balance` operations, where a `withdraw` is a strongly consistent operation that succeeds only if there are sufficient funds in the account. There are two anomalies associated with `get_balance` in this program: (i) when a user performs a `deposit`, which is however, not reflected in the subsequent `get_balance` (ii) when a `get_balance` witnesses a `withdraw` effect, without witnessing all the `deposit` effects that were visible to it, which may result in `get_balance` returning a negative balance. As it is presented in Fig. 8, in order to preempt these anomalies, `get_balance` requires both RMW and 2VIS guarantees.

To evaluate its performance, we deploy SYNCOPE on a cloud cluster, consisting of three fully replicated Cassandra replicas, running on separate machines within the same datacenter. Each machine is instantiated with a SYNCOPE shim

Benchmark	Consistency	Description
Counter	MR	Monotonically increasing counter, e.g. YouTube's watch count
DynamoDB	RMW	Integer register allowing various conditional puts and gets
Online Store	RMW	Online store with shopping carts and modifiable item prices
Bankaccount	2VIS $\wedge$ RMW	Offering deposit, withdraw and get balance operations
Shopping List	MW $\wedge$ RMW	A shopping list with concurrent adds and deletes functionality
Microblog	MW, RMW	A Twitter-like application modeled after Twissandra
Rubis	RMW, RMW $\wedge$ 2VIS	eBay-like application with browsing, supporting user wallet

Fig. 8: Fine-grained consistency requirement in benchmark programs

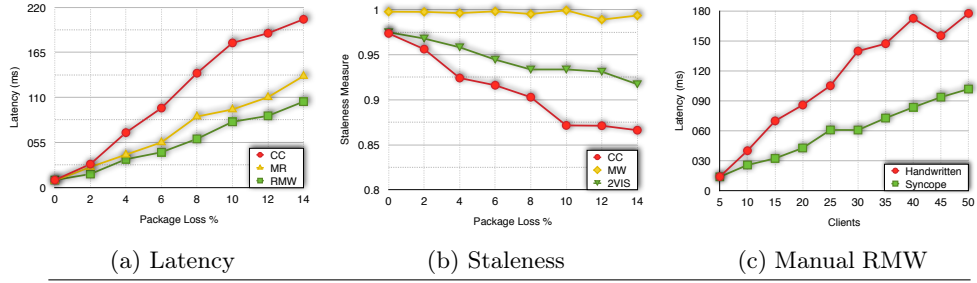

Fig. 9: A distributed application for comment section management

layer, that responds to clients, which are instantiated on a virtual machine co-located with one of the replicas on a machine. We deploy the cluster on three **m4.4xlarge** Amazon EC2 instances in US-West (Oregon) region, with inter-machine communication time of 5ms.

Since Cassandra is developed over TCP connections for replica communications, we found all messages being delivered with no loss and in order, making it much more consistent than EC, and masking out the differences between our fine-grained consistency guarantees. Consequently, to simulate a realistic EC environment, we inject random message losses at the shim layers, where a message delivery is delayed for 1 second in case it is lost.

Fig. 9(a) and 9(b) represent our experimental results, with a workload generated by 50 concurrent clients repeatedly running sessions, each composed of three operations, where operations uniformly choose from 5 objects and are performed under the specified consistency level. We increased the percentage of delayed messages from 0 to 14, and each experiment ran for 100 repeated sessions per client, where the staleness measure is the ratio of the number of visible effects, to all available effects, averaged on all operations at all replicas.

The first set of experiments, measures the client perceived latency for three different LB contracts all implemented in SYNCOPE. As expected, causal consistency, the strongest consistency level our tool can enforce, experiences the largest increase in latency. The results show 17% and 67% increase in latency between (RMW-MR) and (MR-CC) at only 4 percent message loss. These numbers go up to respectively 18% and 87% at 10 percent message loss.

## B Proofs

Here, we present the detailed proofs of the theorems of the paper. Let's first present a useful lemma:

**Lemma 1.** *For all relations  $R$  and execution steps:*

$$(\mathbf{E}, op_{<s, i>}) \xrightarrow{V} (\mathbf{E}', \eta)$$

*interpretatin of  $R$  under  $E$  and  $E'$  only differs considering  $\eta$ , i.e.  $a, b \neq \eta \Rightarrow (R'(a, b) \Leftrightarrow R(a, b))$*

*Proof.* We only prove  $\Rightarrow$ , the other part can be done similarly. We have the following goal and hypotheses:

$$\begin{aligned} H_0 &: (\mathbf{E}, op_{<s, i>}) \xrightarrow{V} (\mathbf{E}', \eta) \\ H_1 &: a, b \neq \eta \\ H_2 &: R'(a, b) \\ G_0 &: R(a, b) \end{aligned}$$

Now by destructing  $R$  we have the followings from new hypothesis and goal:

$$\begin{aligned} H_3 &: (\text{trunc}(R); r)'(a, b) \\ G_1 &: (\text{trunc}(R); r)(a, b) \end{aligned}$$

which can be rewritten by the definition to get that  $y$  exists s.t.

$$\begin{aligned} H_4 &: (\text{trunc}(R))'(a, y) \\ H_5 &: r'(y, b) \\ G_1 &: \exists x. (\text{trunc}(R))(a, x) \wedge (r)(x, b) \end{aligned}$$

Now we instantiate the goal with  $y$  itself and by using induction on the length of  $R$ , the first conjunct is proved, and we are left with the following:

$$\begin{aligned} H_6 &: r'(y, b) \\ G_1 &: r(y, b) \end{aligned}$$

Now by inversion on  $H_0$  we get two cases, at both of which the following can be derived. (In one case  $V$  should be replaced by  $V'$  but has no effect on the proof):

$$\begin{aligned} H_7 &: \text{vis}' = \text{vis} \cup V \times \{\eta\} \\ H_8 &: \text{so}' = \text{so}' = \text{so} \cup \{(\eta', \eta) \mid \eta' \in \mathbf{A}_{(\text{SessID}=s)}\} \end{aligned}$$

Now, because of  $H_1$  (and the fact that  $y \neq \eta$ ) it is easy to get the following from  $H_7$  and  $H_8$ :

$$\begin{aligned} H_9 &: \text{vis}(y, b) \Rightarrow \text{vis}(y, b) = \\ H_{10} &: \text{so}(y, b) \Rightarrow \text{so}(y, b) = \end{aligned}$$

Which directly prove the goal, after destructing  $r$ .

### B.1 Proof of Theorem 1

(Part i) We have the following two hypotheses and the goal:

$$\frac{H_0 : (\mathbf{E}, op_{<s,i>}) \xrightarrow{V} (\mathbf{E}', \eta) \quad H_1 : V \text{ is } \psi\text{-consistent under } \mathbf{E}}{G_0 : V \cup \{\eta\} \text{ is } \psi\text{-consistent under } \mathbf{E}'}$$

Rewriting the definition in  $G_0$  results in the following. We denote the interpretation of  $R$  under  $E'$  as  $R'$ :

$$G_1 : \forall(b \in V \cup \{\eta\}). \forall(a \in E'.A). R'(a, b) \Rightarrow a \in V \cup \{\eta\}$$

By intros we have:

$$\frac{H_2 : b \in V \cup \{\eta\} \quad H_3 : a \in E'.A \quad H_4 : R'(a, b)}{G_2 : a \in V \cup \{\eta\}}$$

by inversion on  $H_0$ , there is two cases, in case one (UB reduction) we have the following:

$$T_1 : V' \vdash (\mathbf{E}, op_{<s,i>}) \hookrightarrow (\mathbf{E}', \eta)$$

by inversion on  $T_1$  we will have the following:

$$T_2 : E'.A = E.A \cup \{\eta\}$$

Since the other case (LB reduction) also includes similar premises which yields  $T_2$ , we can add it to the hypothesis:

$$H_5 : E'.A = E.A \cup \{\eta\}$$

by rewriting  $H_5$  in  $H_3$  and by inversion, we get two cases:  $a = \eta$  and  $a \in E.A$ . The first case immediatly proves  $G_2$ , so we only consider the second case where we have:

$$H_6 : a \in E.A$$

Now, by inversion on  $H_2$ , we have two cases:

– **Case 1:**

$$b \in V$$

by inversion in  $H_1$  we have:

$$H_7 : \forall(x \in V). \forall(y \in E.A). R(y, x) \Rightarrow y \in V$$

by instantiation with a and b:

$$H_8 : R(a, b) \Rightarrow a \in V$$

Now by applying the lemma 1 on  $H_4$  we get that  $R(a, b)$  holds (since  $a, b \neq \eta$ ), which can be applied on  $H_8$  to get  $a \in V$  which proves the goal  $G_2$ .

– **Case 2:**

$$\begin{array}{l} H_9 : b = \eta \\ \text{(by rewriting } H_9 \text{ in } H_4) \quad H_{10} : R'(a, \eta) \end{array}$$

Now we use inversion on  $H_0$  and get two cases: (LB exec) and (UB exec)

– **SCase (LB exec):** we have  $H_{11}$  and  $H_{12}$  from the reduction rule premises:

$$\begin{array}{l} H_{11} : R_V^{-1}(\eta) = R_{E'.A}^{-1}(\eta) \\ H_{12} : R_V^{-1}(\eta) \subseteq V \end{array}$$

now from  $H_{10}$  we have  $H_{13}$  which can be rewritten by  $H_{11}$  to get  $H_{H14}$ :

$$\begin{aligned} H_{13} : a &\in R_{E'.A}^{-1}(\eta) \\ H_{14} : a &\in R_V^{-1}(\eta) \end{aligned}$$

The goal  $G_2$  is now proved from  $H_{12}$  and  $H_{14}$ .

– **SCase (UB exec)**: We have the following from the premises:

$$\begin{aligned} H_{15} : V' &= \lfloor V \rfloor_{\max} \\ H_{16} : V' &\subseteq V \end{aligned}$$

now destruct  $R$ , the only non-trivial cases are  $(R = \text{trunc}(R); \text{vis})$  and  $(R = \text{vis})$ :

**SSCase**  $(R = \text{trunc}(R); \text{vis})$ :

From  $H_{10}$  we get  $H_{17}$  which based on the definition, yields that there exists  $c$  such that  $H_{18}$ ,  $H_{19}$  and  $H_{20}$  hold:

$$\begin{aligned} H_{17} : a &\in (\text{trunc}(R)'; \text{vis}')_{E'.A}^{-1}(\eta) \\ H_{18} : c &\in \text{vis}'^{-1}(\eta) \\ H_{19} : a &\in \text{trunc}(R)'^{-1}(c) \\ H_{20} : \text{vis}'^{-1}(\eta) &\subseteq E'.A \end{aligned}$$

from  $H_{15}$  we have:

$$H_{21} : (\text{trunc}(R))_V^{-1}(V') \subseteq V'$$

Now from  $H_{18}$  is straightforward to get:

$$H_{22} : c \in V'$$

which after appying the lemma 1 on  $H_{19}$ , and by  $H_{21}$  yields the following, which proves the goal  $G_2$ :

$$H_{23} : a \in V'$$

**SSCase**  $(R = \text{vis})$ : From  $H_{10}$  we get that  $\text{vis}'(a, \eta)$ , which -with a similar argument to the previous subcase- yields the following and the goal is proved:

$$H_{24} : a \in V'$$

QED.

### (Part ii)

For this part we have the following hypothesis and the goal:

$$\begin{aligned} H_0 : (\mathbf{E}, \text{op}_{<s, i>}) &\xrightarrow{V} (\mathbf{E}', \eta) \\ G_0 : E' &\models [\eta/\hat{\eta}] \end{aligned}$$

By inversion on  $H_0$ , we have two cases:

**Case1** (UB exec):

$$\begin{aligned} H_1 : r_k &= \text{vis} \\ H_2 : V &\subseteq E.A \\ H_3 : V' &= \lfloor V \rfloor_{\max} \\ H_4 : V' &\vdash (\mathbf{E}, \text{op}_{<s, i>}) \hookrightarrow (\mathbf{E}', \eta) \end{aligned}$$

The goal  $G_0$  can be rewritten as:

$$G_1 : E' \models \forall a. a \xrightarrow{R} \eta \Rightarrow a \xrightarrow{\text{vis}} \eta$$

Since the  $E'.A$  gives the interpretation for the universe of quantification:

$$G_2 : \forall (a \in E'.A). E' \models a \xrightarrow{R} \eta \Rightarrow a \xrightarrow{vis} \eta$$

by intros:

$$\begin{aligned} H_5 &: a \in E'.A \\ G_3 &: E' \models a \xrightarrow{R} \eta \Rightarrow a \xrightarrow{vis} \eta \end{aligned}$$

Now since  $((\mathcal{M} \models A \Rightarrow B) \Leftrightarrow (\mathcal{M} \models A \Rightarrow \mathcal{M} \models B))$  we can rewrite  $G_3$  as:

$$G_4 : (E' \models a \xrightarrow{R} \eta) \Rightarrow (E' \models a \xrightarrow{vis} \eta)$$

intros:

$$\begin{aligned} H_6 &: E' \models a \xrightarrow{R} \eta \\ G_5 &: E' \models a \xrightarrow{vis} \eta \end{aligned}$$

Now we use the interpretation given by  $E'$ , to rewrite the relations as follows. Note that we denote the interpretation of  $R$  under  $E'$  as  $R'$  and  $E.vis$  as  $vis'$ .

$$\begin{aligned} H_7 &: R'(a, \eta) \\ G_6 &: vis'(a, \eta) \end{aligned}$$

by inversion on  $H_4$ :

$$H_8 : vis' = vis \cup V' \times \{\eta\}$$

Now since  $\eta$  is a fresh effect, we get that  $a \in V' \Rightarrow vis'(a, \eta)$  which can be applied to  $G_6$  to get the following:

$$G_7 : a \in V'$$

Now, destructing  $R$  yields multiple cases, only one of which is non-trivial:  $R = \text{trunc}(R); vis$ , which can be rewritten in  $H_7$  to get:

$$H_9 : (\text{trunc}(R); vis)'(a, \eta)$$

Now we can rewrite the definition in  $H_9$ , and derive that there exists  $b$  such that:

$$\begin{aligned} H_{10} &: \text{trunc}(R)'(a, b) \\ H_{11} &: vis'(b, \eta) \end{aligned}$$

Now using a similar argument, from  $H_8$  and  $H_{11}$  we get:

$$H_{12} : b \in V'$$

Now by applying the lemma 1 on  $H_{10}$  we get:

$$H_{13} : \text{trunc}(R)(a, b)$$

since we have  $V' \in [V]$ , we get the following:

$$H_{14} : \forall (x \in V'). (\text{trunc}(R))_{E.A}^{-1}(V') \Rightarrow x \in V'$$

which yields the following from  $H_{12}$  and  $H_{13}$ :

$$H_{15} : a \in V'$$

which proves the goal  $G_7$ .

**Case2** (LB exec):

We prove this case by induction on the length of the given relation  $R$ . We have the followings, from the premises of the reduction rule:

$$\begin{aligned} H_1 &: r_k = \text{so} \\ H_2 &: V \subseteq E.A \\ H_3 &: R_V^{-1}(\eta) = R_{E.A}^{-1}(\eta) \\ H_4 &: R_V^{-1}(\eta) \subseteq V \\ H_5 &: V \vdash (\mathbf{E}, op_{<s,i>}) \hookrightarrow (\mathbf{E}', \eta) \end{aligned}$$

Using the same argument as the previous section, we get the following new goal and hypotheses:

$$\begin{aligned} H_6 &: a \in E'.A \\ H_7 &: R'(a, \eta) \\ G_1 &: \text{vis}'(a, \eta) \end{aligned}$$

We now destruct  $R$  to get  $H_8$  from  $H_7$ , and rewrite the definition in it to get the next two hypotheses. Note that by destructing  $R$ , there are only two non-trivial cases  $R = \text{trunc}(R); \text{so}$  and  $R = \text{so}$ , which we are only considering the former, since the latter can be proved similarly.

$$\begin{aligned} H_8 &: (\text{trunc}(R); \text{so})'(a, \eta) \\ H_9 &: \text{trunc}(R)'(a, b) \\ H_{10} &: \text{so}'(b, \eta) \end{aligned}$$

Now, from the previous section we know that  $(\text{so}')^{-1}(\eta) \subseteq V$  which yields the following from  $H_{10}$ :

$$H_{11} : b \in V$$

The goal is proved by the induction hypothesis,  $H_9$  and  $H_{11}$ .

QED.

## B.2 Proof of Theorem 2

We prove the theorem by contradiction:

$$\begin{aligned} H_0 &: (\mathbf{E}, op_{<s,i>}) \xrightarrow{V} (\mathbf{E}', \eta) \\ H_1 &: a \in V \\ H_2 &: (a, \eta) \notin E'.\text{vis} \\ H_3 &: (E'.A, E'.\text{vis} \cup \{(a, \eta)\}, E'.\text{so}) \models \psi[\eta/\hat{\eta}] \\ H_4 &: (\text{trunc}(R)_V^{-1}(a) = \text{trunc}(R)_{E.A}^{-1}(a)) \\ G_0 &: \perp \end{aligned}$$

Now we call  $(E'.A, E'.\text{vis} \cup \{(a, \eta)\}, E'.\text{so})$  as  $E''$  and derive the following from  $H_3$ :

$$H_5 : E'' \models \forall x.x \xrightarrow{R} \eta \Rightarrow x \xrightarrow{\text{vis}} \eta$$

because  $E''$  defines the universe of quantification (and since  $E''.A = E'.A$ ), we get the following:

$$H_6 : \forall (x \in E'.A). E'' \models x \xrightarrow{R} \eta \Rightarrow x \xrightarrow{\text{vis}} \eta$$

and is rewritten as the following:

$$H_7 : \forall (x \in E'.A). (E'' \models x \xrightarrow{R} \eta) \Rightarrow (E'' \models x \xrightarrow{\text{vis}} \eta)$$

Now by inversion on  $H_0$  we get two cases, one of which is trivial. We skip the formal proof for it but it is easy to see that in [LB exec] case, ALL effects in  $V$  are made

visible to  $\eta$ , so the set is trivially maximal, i.e.  $H_1$  and  $H_2$  yield  $\perp$ . For the other case (UB exec), we get the following:

$$\begin{aligned} H_8 : V' &= \lfloor V \rfloor_{\max} \\ H_9 : V' &\vdash (\mathbf{E}, op_{<s, i>}) \hookrightarrow (\mathbf{E}', \eta) \end{aligned}$$

by inversion on  $H_9$  we get  $H_{10}$  and from that and from  $H_2$ , following a similar argument from the proof of theorem 1, we get  $H_{11}$ :

$$\begin{aligned} H_{10} : \mathbf{vis}' &= \mathbf{vis} \cup V' \times \{\eta\} \\ H_{11} : a &\notin V' \end{aligned}$$

Now by denoting the interpretation of  $R$  under  $E''$  as  $R''$ ,  $H_7$  can be rewritten as follows:

$$H_{12} : \forall (x \in E'.A). R''(x, \eta) \Rightarrow \mathbf{vis}''(x, \eta)$$

Now by inversion on  $H_8$ , we get the following:

$$\begin{aligned} H_{13} : V' &\in \lfloor V \rfloor \\ H_{14} : \exists V'' \in \lfloor V \rfloor. |V''| &> |V'| \\ (\text{from } H_{13}) \quad H_{15} : V' &\subseteq V \wedge (\text{trunc}(R))_V^{-1}(V') \subseteq V' \wedge \\ &(\text{trunc}(R))_V^{-1}(V') = (\text{trunc}(R))_{E.A}^{-1}(V') \end{aligned}$$

Now we can destruct  $R$ , where we get multiple cases, only two of which are non-trivial, ( $R = \mathbf{vis}$ ) and ( $R = \text{trunc}(R); \mathbf{vis}$ )

- **Case1**( $R = \mathbf{vis}$ ):  
 $\text{trunc}(R) = \mathbf{null}$ , thus  $V$  itself satisfies the requirements in  $H_{15}$  and we get that ( $V = \lfloor V \rfloor_{\max}$ ) and the following holds:

$$H_{16} : V = V'$$

which results in contradiction from  $H_1$  and  $H_{11}$ .

- **Case2**( $R = \text{trunc}(R); \mathbf{vis}$ ):  
 Since  $|V' \cup \{a\}| > |V'|$  we have the following:

$$H_{17} : (V' \cup \{a\}) \notin \lfloor V \rfloor$$

which based on the definition yields that the conditions for holding the above relation are not true, i.e.

$$\begin{aligned} H_{18} : \neg((V' \cup \{a\}) &\subseteq V \wedge (\text{trunc}(R))_V^{-1}(V' \cup \{a\}) \subseteq (V' \cup \{a\}) \wedge \\ &(\text{trunc}(R))_V^{-1}(V' \cup \{a\}) = (\text{trunc}(R))_{E.A}^{-1}(V' \cup \{a\})) \end{aligned}$$

or equally:

$$\begin{aligned} H_{19} : (V' \cup \{a\}) &\not\subseteq V \vee \\ &(\text{trunc}(R))_V^{-1}(V' \cup \{a\}) \not\subseteq (V' \cup \{a\}) \vee \\ &(\text{trunc}(R))_V^{-1}(V' \cup \{a\}) \neq (\text{trunc}(R))_{E.A}^{-1}(V' \cup \{a\}) \end{aligned}$$

By inversion on the above, we get three cases, two of which are trivial. The last conjunct can't hold because of  $H_4$  and the first one also contradicts with  $H_1$  and  $H_{15}$ . Thus, we are left with only one case:

$$H_{20} : (\text{trunc}(R))_V^{-1}(V' \cup \{a\}) \not\subseteq (V' \cup \{a\})$$

Now, from the second conjunct in  $H_{15}$  we know that it should be the case that:

$$(\text{from } H_{15} : (\text{trunc}(R))_V^{-1}(V') \subseteq V') \quad H_{21} : ((\text{trunc}(R))_V^{-1}(a) \not\subseteq (V' \cup \{a\}))$$

The above hypothesis yields the existence of  $c \neq a$  such that:

$$\begin{aligned} H_{22} &: c \in (\text{trunc}(R))_V^{-1}(a) \\ H_{23} &: c \notin V' \end{aligned}$$

Now, by rewriting  $(R = \text{trunc}(R); \text{vis})$  in  $H_{12}$  we get  $H_{24}$ , which can be rewritten again into  $H_{25}$  from the definition:

$$\begin{aligned} H_{24} &: \forall(x \in E'.A).((\text{trunc}(R); \text{vis})''(x, \eta) \Rightarrow \text{vis}''(x, \eta)) \\ H_{25} &: \forall(x \in E'.A).(\exists b. \text{trunc}(R)''(x, b) \wedge \\ &\quad \text{vis}''(b, \eta) \Rightarrow \text{vis}''(x, \eta)) \end{aligned}$$

Now, we instantiate  $H_{25}$  with  $x = c$ :

$$H_{26} : \exists b. \text{trunc}(R)''(c, b) \wedge \text{vis}''(b, \eta) \Rightarrow \text{vis}''(c, \eta)$$

we can replace  $\text{trunc}(R)''$  with  $\text{trunc}(R)'$  in above definition, since from  $H_3$ , the only difference in interpretation under  $E'$  and  $E''$  is the extra element  $(a, \eta)$  in  $E''.\text{vis}$  which does not effect  $\text{trunc}(R)''(c, b)$ :

$$H_{27} : \exists b. \text{trunc}(R)'(c, b) \wedge \text{vis}''(b, \eta) \Rightarrow \text{vis}''(c, \eta)$$

Moreover, since  $c \neq a$ , we can replace  $\text{vis}''(c, \eta)$  with  $\text{vis}'(c, \eta)$ :

$$H_{28} : \exists b. \text{trunc}(R)'(c, b) \wedge \text{vis}''(b, \eta) \Rightarrow \text{vis}'(c, \eta)$$

From  $H_{15}$  and  $H_{22}$  we get  $H_{29}$ , and  $H_{30}$  also holds trivially from  $H_3$ :

$$\begin{aligned} H_{29} &: \text{trunc}(R)'(c, a) \\ H_{30} &: \text{vis}''(a, \eta) \end{aligned}$$

which can be used in instantiation of  $H_{28}$  with  $b = a$  and derive the following:

$$H_{31} : \text{vis}'(c, \eta)$$

However, we know -from the previously explained argument- that  $H_{31}$  results in  $H_{32}$ , which results in contradiction with  $H_{23}$ .

$$H_{32} : c \in V'$$

QED.

### B.3 Proof of Theorem 3

Before proving the theorem, we first present and prove a useful lemma and then we will present a new definition, regarding sets of effects.

---

**Lemma 2.** *Under an execution state  $E$  and for a given set  $S \subseteq E.A$ , if  $S$  is  $\psi$ -consistent under  $E$ , then  $\forall(x \in S).R_S^{-1}(x) \subseteq S$  under  $E$ .*

*Proof.*

$$\begin{aligned} H_0 &: \text{Sis}\psi\text{-consistent} \\ G_0 &: \forall(x \in S).R_S^{-1}(x) \subseteq S \end{aligned}$$

after intros:

$$\begin{aligned} H_1 &: x \in S \\ G_1 &: R_S^{-1}(x) \subseteq S \end{aligned}$$

inversion on  $H_0$  gives the following:

$$H_2 : \forall(\eta \in S). \forall(a \in E.A). R(a, \eta) \Rightarrow a \in S$$

which can be rewritten to:

$$H_3 : \forall(\eta \in S). R^{-1}(\eta) \subseteq S$$

however, since  $S \subseteq E.A$  then<sup>8</sup>:

$$H_4 : \forall(a \in E.A). R_S^{-1}(a) \subseteq R^{-1}(a)$$

Now we can instantiate  $H_3$  and  $H_4$  into:

$$\begin{aligned} H_5 : R^{-1}(x) &\subseteq S \\ H_6 : R_S^{-1}(x) &\subseteq R^{-1}(x) \end{aligned}$$

which trivially yields  $G_1$  and the proof is completed.

QED.

**Definition 1.** We define the complement of a given set of effects  $S$  (under an execution state  $E$ ) as the super set of  $S$ , containing ALL the mid-level effects required to determine ALL the dependencies of the effects in  $S$ , i.e.

$$S' \in [S] \iff R_{S'}^{-1}(S) = R_{E.A}^{-1}(S)$$

Now, using the above theorem and lemma, we present the proof of the theorem 3, which starts by listing the following hypotheses and the goal:

$$\begin{aligned} H_0 : S &\vdash (\mathbf{E}, op_{<s,i>}) \hookrightarrow (\mathbf{E}', \eta) \\ H_1 : S \cup \{\eta\} &\text{ is } \psi\text{-consistent} \\ G_0 : \exists E'' . \exists \eta' . \exists V . ((\mathbf{E}, op_{<s,i>}) &\xrightarrow{V} (\mathbf{E}'', \eta')) \end{aligned}$$

Now, by destructing  $R$  we get two non-trivial cases:

– **Case1**( $R = \text{trunc}(R); \text{vis}$ ):

In this case<sup>9</sup>, we generate the premises of the  $[\text{UB EXEC}]$  to achieve the goal as follows. Firstly, we define  $S'$  and present  $\eta'$ :

$$\begin{aligned} H_3 : S' &= \lfloor S \rfloor_{\max} \\ H_4 : \eta' &= (s, op, F_{op}(S')) \end{aligned}$$

Moreover, we will define the followings, which will be used when presenting  $E''$ :

$$\begin{aligned} H_5 : \text{so}'' &= \text{so} \cup A_{(\text{sessID}=s)} \times \{\eta'\} \\ H_6 : \text{vis}'' &= \text{vis} \cup S' \times \{\eta'\} \\ H_7 : A'' &= E.A \cup \{\eta'\} \end{aligned}$$

Now we present  $V$  and  $E''$  as follows and rewrite the goal:

$$\begin{aligned} H_8 : V &= S \\ H_9 : E'' &= (A'', \text{so}'', \text{vis}'') \\ G_1 : (\mathbf{E}, op_{<s,i>}) &\xrightarrow{V} (\mathbf{E}'', \eta') \end{aligned}$$

<sup>8</sup> we skip the formal proof of this claim, however, since the only difference in the definitions of  $R^{-1}$  and  $R_S^{-1}$  is the extra requirement about mid-level effects in the latter, it should be a subset of the former.

<sup>9</sup> Note that in this case the goal  $G_0$ , trivially holds. That is because the contract in this case is  $[\text{UB}]$ , which represents executions without blocking or waiting, that can always make progress by showing *some* set of effects to the operations

by applying [UB EXEC] on  $G_1$  we get the following new goals (after rewriting  $H_9$  and  $H_3$ ):

$$\begin{aligned} G_2 : r_k &= \text{vis} \\ G_3 : S &\subseteq E.A \\ G_4 : S' &= \lfloor S \rfloor \\ G_5 : S' \vdash (E, op_{<s,i>}) &\hookrightarrow (E'', \eta') \end{aligned}$$

first three goals are proved via the assumptions, and the last one can be easily shown to hold by applying [OPER] and deriving the following new goals:

$$\begin{aligned} G_6 : S' &\subseteq E.A \\ G_7 : F_{op}(S') &= v \\ G_8 : \eta' &= (s, op, v) \\ G_9 : \eta &\notin S' \\ G_{10} : E''.A &= E.A \cup \{\eta'\} \\ G_{11} : E''.\text{vis} &= E.\text{vis} \cup S' \times \{\eta\} \\ G_{12} : E''.\text{so} &= E.\text{so} \cup (A_{(\text{sessID}=s)}) \times \{\eta\} \end{aligned}$$

all the above goals have already been shown in the assumptions and the case is proved.

– **Case2**( $R = \text{trunc}(R); \text{so}$ ):

Similarly in this case we define the following:

$$H_{13} : V = \lceil S \cup \{\eta\} \rceil$$

which yields:

$$H_{14} : \forall (x \in S \cup \{\eta\}). R_V^{-1}(x) = R_{E'.A}^{-1}(x)$$

and also:

$$H_{15} : R_V^{-1}(\eta) = R_{E'.A}^{-1}(\eta)$$

Similar to the previous case, we now define the followings:

$$\begin{aligned} H_{16} : \eta' &= (s, op, F_{op}(V)) \\ H_{17} : \text{so}'' &= \text{so} \cup A_{(\text{sessID}=s)} \times \{\eta'\} \\ H_{18} : \text{vis}'' &= \text{vis} \cup V \times \{\eta'\} \end{aligned}$$

Now we present  $E''$  as follows and rewrite the goal:

$$\begin{aligned} H_{19} : E'' &= (A'', \text{so}'', \text{vis}'') \\ G_1 : (E, op_{<s,i>}) &\xrightarrow{V} (E'', \eta') \end{aligned}$$

by applying [LB EXEC] on  $G_1$  we get the following new goals

$$\begin{aligned} G_2 : r_k &= \text{so} \\ G_3 : V &\subseteq E.A \\ G_4 : R_V^{-1}(\eta') &= R_{E''.A}^{-1}(\eta') \\ G_5 : R_V^{-1}(\eta') &\subseteq V \\ G_6 : V \vdash (E, op_{<s,i>}) &\hookrightarrow (E'', \eta') \end{aligned}$$

Now,  $G_2$  and  $G_3$  are trivially proved from the assumptions, and  $G_6$  also can be easily proved following the argument from the previous case. We prove  $G_4$  and  $G_5$ , by a new claim that  $R_{E'.A}^{-1}(\eta) = R_{E''.A}^{-1}(\eta')$  which will be proved separately. Thus, we can rewrite the goals and add the new claim:

$$\begin{aligned} G_7 : R^{-1}(\eta) &= R_{E'.A}^{-1}(\eta) \\ G_8 : R^{-1}(\eta) &\subseteq V \\ G_9 : R_{E'.A}^{-1}(\eta) &= R_{E''.A}^{-1}(\eta') \end{aligned}$$

Now  $G_7$  is equal to the assumption  $H_{15}$ , and  $G_8$  is the direct result of applying the lemma 2 on  $H_1$ . Now by rewriting  $R = \text{trunc}(R); \text{so}$  in  $G_9$  we have the following:

$$G_{10} : (\text{trunc}(R); \text{so})_{E'.A}^{-1}(\eta) = (\text{trunc}(R); \text{so})_{E''.A}^{-1}(\eta')$$

Now, note that the only difference in  $E'$  and  $E''$  is in how the update the vis relation from  $E$ , the former makes the set  $S$  visible to the operation and the latter the set  $[S \cup \{\eta\}]$ . Now since the given relation  $R$  ends with an **so** relation, it is straightforward to show that  $G_{10}$  holds and thus the case (and the theorem) is proved.

QED.
